# OF TWO MINDS: SELLING THE RIGHT BRAIN

Popularizers are teaching businessmen to tap the supposed source, of intuition and creativity. But are they pushing science too far?

#### **BY KEVIN McKEAN**

rankly, Jones, your education and background are only average," the personnel officer tells a nervous applicant. "But your brain dominance profile is impressive: strong right hemisphere skills, especially intuition and holistic thinking. That's just the kind of mind we need in this company. I think we can offer you a job!"

That speech probably hasn't been made yet. But it soon could be, if the teachings of a new group of management advisers catch on. These consultants, investment counselors, and other entrepreneurs have set themselves the task of persuading American business to end what they consider to be discrimination against half the human brain—the right half. In the process, they promise, companies can improve working conditions, increase profits, and better withstand the economy's ups and downs.

This unlikely crusade was inspired by pioneering research over the past two decades that has revealed profound differences between the brain's two hemispheres. Work by the Nobel Prize-winning psychobiologist Roger Sperry and others suggests that the left hemisphere is better at verbal, logical, quantitative, and analytical thinking, whereas the right hemisphere is more visually and spatially adroit, more artistic, musical, emotional, and creative. Sperry has gone on to argue that

### BEHAVIOR

Western culture itself, with its heavy emphasis on "left brain" talents like logic and reason, is subtly biased against the right. That notion has prompted a number of educators to seek ways of redressing the balance. For example, Betty Edwards, a California art teacher, in her 1979 bestseller Drawing on the Right Side of the Brain, exhorts students to suppress the verbal left hemisphere and turn on the artistic right as a means of learning to draw.

ow that this right-brain movement, as it might be called. is spreading to the corporate world, its advocates are telling the heads of some of the nation's largest companies to stop relying so much on leftbrain thinking, and instead to develop the mental "right stuff" that they claim will lead to greater creativity and entrepreneurial zeal. In addition, they say, executives can manage their subordinates better if they recognize which of them have predominantly left- or right-brain skills. "Often, the organization is at fault for not putting left- and right-brain people together very well," explains Weston Agor, director of the masters of public administration program at the University of Texas at El Paso, and author of Intuitive Management: Integrating Left and Right Brain Management Skills (1984). Agor and others say that brain dominance-the notion that some people tend to think more with their right hemispheres, others with the left-should be considered when a company hires, fires, promotes, forms committees, or assigns work.

The right-brain movement is not without critics, of course-notably some of the most prominent scientists whose work it's based on. The movement's claims, they say, go well beyond what can be proved in the lab, and some of the methods advocated for increasing creativity are downright ludicrous. "It's pure nonsense," says Michael Gazzaniga, of Cornell University Medical College in New York, who assisted Sperry with much of the original splitbrain research. "I take my hat off to some of these people for making money out of this deal. But the simple fact is that you don't have to invoke one cent's worth of experimental psychological data or neuroscience to make the observation that there are some people in this world who are terribly intuitive and creative, and some who aren't."

That hasn't stopped right-brain proponents from making inroads in American business—and doing a little business for themselves along the way. Agor, for example, earns \$1,000 apiece for the dozen or so day-long seminars he gives each year. Inferential Focus, a New York consulting firm, charges its 75 corporate clients about \$18,000 a year each for alerting them to new social and economic trends that it identifies by using "creative rightbrain processes," as one company officer puts it. And Ned Herrmann, perhaps the movement's leading figure, says his Whole Brain Corporation will

go back to the scientific work that began at the California Institute of Technology in the early 1960s. Sperry and his students—Gazzaniga, Jerre Levy, and others—were studying patients who had undergone highly experimental brain surgery for epilepsy. Surgeons had cut the corpus callosum, an arching bundle of nerve fibers that connects the left and the right halves of the cerebrum, the largest and most sophisticated part of the brain. The surgery was intended to isolate the two cerebral hemispheres so that epilep-

in order to determine their "brain dominance profile."

Does the right-brain movement really have something to offer, or is it just pseudo science with neurological trappings? The implications of the answer go far beyond the corporate corridors: if the message is valid for business, it offers powerful insights into all manner of thinking. If not, it's probably just another fad.

To answer that question, it helps to

leptic attacks without visible side effects

But Sperry soon learned that the lack of complications was an illusion. In effect the surgery had left the patients with two brains inside a single skull. The duality didn't show up in normal behavior, since neither side was in conflict with the other But when he and his colleagues devised ways of communicating with one hemisphere at a time, they found that the two half-brains differed profoundly. Their studies relied on a basic fact of neuroanatomy: nerve connections throughout the body cross at the midline, which means that sensation and movement on each side of the body are governed by the opposite side of the brain. In a typical study, Sperry and Gazzaniga flashed images to one side or the other of a patient's visual field so that the image would be seen by only one hemisphere of the brain (see illustration, below). When the verbal left hemisphere received the image, the patient could name what he saw. When the nonverbal right hemisphere received it, the patient couldn't name the object, but could select it from among other objects by using his left arm-the one controlled by the nonverbal side. "In many respects, Sperry wrote, "each disconnect-

experiments showed that what the right hemisphere lacks in eloquence it more than makes up for in visual, spatial, and musical prowess. In one dramatic instance, Sperry and Gazzaniga asked one of their "split brain" patients to work a simple puzzle with his right hand. This hand, controlled by the supposedly dominant left hemisphere, made such a fumbling, ineffectual mess of it that the scientists had to restrain the left hand forcibly from moving onto the table to help out.

As the experiments progressed, Sperry found himself gaining a new appreciation for the talents of the nonverbal hemisphere, gradually becoming convinced that these abilities are undervalued by societies that emphasize verbal. logical, and quantitative achievement.

The scientists at first assumed that the <sup>vocal</sup> left hemisphere was dominant, the mute right one subordinate.\* That assumption proved simplistic. Subsequent

handers is controlled by the left hemisphere. Of the remainder, about half show right-hemisphere control of speech, and half have control shared by the two hemispheres.

"The main theme to emerge," Sperry wrote in 1973, "is that . . . our educational system, as well as science in general, tends to neglect the nonverbal form of intellect."

In Ned Herrmann, this message found receptive ears. "Even as a kid," he says, "I sensed this curious duality of loving math and science, but also music and art." Herrmann had been a double major in physics and music at Cornell. When he got interested in brain research in 1976, he was both chief of manager education at General Electric and president of the Stamford (Conn.) Art Association. "I'd been responding to the urges that I felt within me all my life," Herrmann says, "but now I saw that they came from opposite sides of the brain."

s Herrmann devoured brain research literature, he became convinced that the distinctions seen in the split-brain patients prevail in normal people too. Indeed, he decided, most people lean toward one or the other style of thinking. Either they're logical, verbal, and analytical-left-brain types who become lawyers, accountants, supervisors, or engineers, or else they're right-brainers who rely for guidance on leaps of intuition and gut feeling-the poets, dreamers, salesmen, and entrepreneurs of this world.

What corporations need, Herrmann decided, is a simple way to find out who is which. He devised a questionnaire to measure a person's "preferred mode of thinking," and began giving it to people at his workshops, at GE and elsewhere, on creativity and the right side of the brain. Some of the questions were drawn from the new brain research: one, for example, asked whether a person held a pen pointed towards or away from his body. (Levy had suggested that the control of language in people who hold their pens pointed toward them may reside in the hemisphere on the same side as their writing hand.) Other questions simply asked a person to choose between right-brainleft-brain dichotomies-for example, is he more creative or more logical, more emotional or more controlled?

Today, the Herrmann questionnaire has grown to a glossy 120-item survey-"Don't call it a test," he says, "because that has a connotation of right or wrong." It's published by the Whole Brain Corporation, the company he helped found two years ago after leaving GE. Whole Brain charges \$50 to analyze each questionnaire (\$40 each for ten or more). Or, for \$1,250. Herrmann's staff will teach you to analyze the surveys yourself, provided you send

him a copy of each result for research purposes. Herrmann says that more than 100,000 people have now taken it. (To assess your own brain style, at no additional cost, see the questionnaire on pages 40 and 41.)

Herrmann says his survey reveals that different patterns of brain dominance lead to distinctly different skills, and thus to different career choices. He adds that a person who winds up in a job for which his brain ill suits him can be miserable. (Herrworkshop," costing \$2,000 plus travel expenses, to a two-and-a-half-day, \$12,000 course in creative problem-solving for up to 20 people. Business is good enough for Whole Brain to maintain a staff of about 30 employees at its offices in Cambridge, Mass. and Lake Lure, N.C. Its clients have included some of the nation's largest firms—IBM, Control Data, GE, Shell, Goodyear, Polaroid, and General Foods.

mann thinks alcoholics tend to be rightbrainers struggling in left-brain slots.) For unknown reasons, husbands and wives often fall at opposite ends of the continuum—"a fact that explains a lot of trouble at home."

People who make the best executives are those who use the two sides of their brains equally, Herrmann says. "Think about the typical chief executive officer's day," he explains. "In the morning, he meets with the finance people and lawyers; at lunch, it's the Henry Moore sculpture people talking about the corporate park; in the afternoon, human resources and new product development. The CEO who's confined to one mode of thinking can't hack it."

To teach executives to broaden their brains, Whole Brain sends instructors to its corporate clients to conduct seminars and measure brain dominance. The seminars range from a half-day "brain update right-brain insights to work? Herrmann offers an example: "Say a business needs to be more entrepreneurial, but its whole corporate culture is anti-entrepreneurial. The culture is the result of the individual mental preferences of its people, and a company composed of ten thousand engineers is going to be cerebral-left\* in focus. If they really want innovation and creativity, they'll need to supplement their staff with more cerebral-right types."

Committees function more effectively with a mix of brain profiles, Herrmann maintains. "If you have a group that's homogeneous for brain dominance, they'll quickly reach a consensus and be satisfied

\* Besides distinguishing between those who favor the right or left hemisphere, Herrmann also divides people into cerebral and limbic (a reference to the limbic system, a set of structures in the brain). Cerebral people are said to be more intellectual, limbic ones more visceral and down to earth. with a relatively mediocre solution because they all think alike. You won't have anybody with a different point of view."

Not all right-brain advocates agree. Weston Agor contends that mixing brain types can lead to trouble. "The problem is that the left-brain people tend to throw cold water on the right-brain people's ideas, and after a while the right-brain people stop trying." He believes it's better to form three committees, one composed of right-brainers, one of left-brainers, and one of people with balanced brains. Then the right-brain group can draw up a list of wild and crazy proposals, the left-brain group can try to shoot them down, and the balanced group can appraise the results and carry out any ideas that survive.

In Agor's view, the most important contribution of the right hemisphere is its ability to infer overall patterns from a few scraps of evidence and jump to intuitive conclusions. "We live in a fast-changing, megatrend world," he says, "and creative intuition may be more important to survival than it was in the past."

> ost of the right-brain theorists are in accord with this, but Agor takes the argument a highly dubious step further.

He believes that, in some people, these powers go beyond mere intuition to encompass what he calls precognition—the ability to see the future by some power resembling ESP. Incredibly, as evidence of this, he says that in his survey of the brain styles of 2,000 top executives, many said they believed in, and claimed to use, ESP. But even Agor acknowledges that this method isn't likely to find much open support in the typical commercial enterprise. "Imagine if you walked into your boss's office tomorrow," he says, "and started talking about some premonitions you had. How far would you get?"

Inferential Focus, the New York consulting firm, takes a more conventional approach to divining the future. One of its founders, Bennett Goodspeed, a marketing expert who died of a heart attack two years ago, argued in his book The Tao Jones Averages: A Guide to Whole-Brained Investing (1983), that rational, calculating, left-hemisphere methods are good for predicting stock prices only as long as the future repeats the pastwhich, of course, it never does. Consequently, the advisers at Inferential Focus pay no attention to price-earnings ratios or computer projections. Instead, they simply read some 175 publications as diverse as FORTUNE, the Oil & Gas Journal, and Soviet Life. All the while, they keep their right hemispheres tuned to the lit-

tle anomalies, the unexpected events, that may signal a shift in business trends.

What kind of anomalies? "A couple of years ago, we began noticing that athletic stores were selling more extra-large jogging suits than there are extra-large joggers," says Charles Hess, one of the company's four consultants. "It seemed that running suits were taking on a new meaning as leisure wear." This bit of evidence meant little by itself, but soon, in Inferential Focus's eyes, it began to fit into a pattern. "Divorce rates were down for the first time in twenty years," says Carol Colman, another consultant. "And board game sales were up," Hess adds. The company's advisers eventually concluded from this and similar information that the "Me Decade" of the 1970s was ending. The 1980s, they said, would see the baby boom generation paying new attention to home and family-a conclusion they say has been borne out since they first reported it to clients in September 1983.

The Inferential Focus advisers also regard showing clients how to think in rightbrain fashion to be part of their mission. "It's not so much teaching people to use their right brain," says Hess. "It's teaching them not to use their left brain, in order that the subtle, nonverbal right brain can have its say."

In this respect, most right-brain instructional methods are broadly similar to those used by Betty Edwards in Drawing on the Right Side of the Brain. In one exercise, students copy a drawing after turning the original upside down. The idea is to make it more difficult for the logical left brain to recognize the subject matter. That way, Edwards says, the right brain is free to draw what it really sees rather than what the left brain thinks it ought to see. Another book intended to teach righthemisphere methods, Marilee Zdenek's The Right-Brain Experience (1983), advises people to free their minds of lefthemisphere inhibitions by studying mandalas (symmetrical designs based on Oriental symbols for the universe), writing with their non-dominant hand, and recording fantasies and dreams.

The interest that corporations have shown in this unconventional, sometimes even bizarre, sort of instruction may result partly from their desire to stay in front of fast-changing economic trends, to say nothing of the competition. Some, like Shell, have established programs to teach their managers to deal with all this. Ray Alvord, an employee development associate at Shell, says, "We felt there needed to be more emphasis on creative thinking, as opposed to the more standard approach of people brought up in a conservative, traditional company." Last year Shell hired Whole Brain to run 15 seminars for some three hundred managers. "The people who attended felt very positive about it," Alvord says. "But as far as a direct impact on our business goes, that's hard to assess. We haven't made any attempt to have people systematically evaluate their subordinates."

Herrmann's presentation was also a hit at Control Data's management training subsidiary in Minneapolis, and even at the monthly department-head meeting of the *Boston Globe.* "It was surprising," says Frank Grundstrom, the newspaper's di-

Sperry, the father of "split brain" research

rector of human resources. "In a group of journalists, I expected a lot more cynicism than I saw. Even the biggest newsroom skeptics came away feeling this guy really had something."

Nonetheless, many research scientists remain unimpressed. "I've gotten so sick of people making piles of money on data that never came out of a lab," complains Jerre Levy, the Sperry collaborator, who's now at the University of Chicago. "They're taking findings with split-brain patients who don't have a corpus callosum and generalizing to normal people." Sally Springer, a psychologist at the State University of New York at Stony Brook and co-author of Left Brain. Right Brain (1985), says flatly that "the evidence we have now is that both hemispheres get involved in virtually everything we do. That doesn't mean these management experts aren't on to something. But to say that it works because of differential use of the two hemispheres goes well beyond what we can prove today."

pringer says that the differences between the hemispheres are largely a matter of degree. The right hemisphere, for example, is often capable of understanding speech, though it can't generate a verbal reply. Even simple relationships, like that between the way a person holds a pen and the location of his verbal hemisphere, are more complicated than was originally thought. Levy says it now appears that writing posture is related to the location of the hemisphere that governs reading, a visual skill, but not other language abilities like speaking or speech comprehension.

Springer's co-author, Georg Deutsch of the University of Texas Medical Branch in Galveston, says that the idea of cerebral dominance had been all but abandoned by scientists before the right-brain movement revived it. "What's come back now is not so much that one or the other side is dominant, but that some people use one side more than the other," he says. "It's the second point that we seriously question. It may be a small part of the constellation of differences these people are talking about. But I suspect that differences within a hemisphere account for more than differences between them."

Deutsch adds that the suggested methods for boosting right-brain thinking are sometimes downright laughable. He cites an article in a management training magazine that suggested playing loud music to drown out parts of a verbal presentation, and lighting incense before a brainstorming session "so you can each read an idea in the smoke." tiple

Even proponents of the right-brain movement acknowledge that providing a scientific foundation for some of their assertions won't be easy. Lawrence Schkade, director of the Center for Research on Information Systems at the University of Texas at Arlington, has been tackling the issue by studying brain waves during mental activity. He found that, when solving problems, accounting majors identified as left-brain types by Herrmann's questionnaire did in fact show greater activity in the left hemisphere, as measured by an electroencephalograph, while art majors had more activity in the right. But when Schkade used the Herrmann survey and others like it to try to predict how a particular person would perform on the EEG, he was never more than 60 per cent accurate.

Sperry himself, an intensely private man who has suffered in recent years from a progressive neurological disease, takes a more cautious stand than some of his disciples. He thinks that the normal differences between the left and right hemispheres "may be exaggerated in some individuals," which suggests that there may in fact be people who could be characterized as left- or right-brain types. But he adds that "many of the practical implications of this cannot as yet be either proved or disproved."

he best way to answer the question of whether nominally rightbrain behavior really flows from the right hemisphere would be to peer inside the living brain while it's at work. Perhaps the best instrument yet devised for doing this is the PET, for positron emission tomography, scanner. This device makes cross-sectional pictures of the brain that indicate the level of mental activity in its parts. The subject is given an injection of a chemical relative of glucose that has been tagged with a fairly harmless short-lived radioisotope. Since brain cells burn glucose for fuel, the most active brain parts take up the most radioactivity, hence appear brightest on the scan.

At the UCLA School of Medicine, neurologist John Mazziotta and his colleagues have used PET scans to establish that the left-right distinctions do in fact hold up for simple activities. Volunteers who listened to a narrator read a Sherlock Holmes story had more activity in the verbal left hemisphere, as expected, while those who listened to musical chords had more activity on the right.

But when Mazziotta switched to a more

complicated task, the results became less clear. He asked volunteers to listen to two series of musical notes and decide whether they were identical. "This is a nonverbal task, " Mazziotta says, "and, by a naïve approach, one might expect it to be handled in the right hemisphere." But only five of the eight volunteers showed more right hemisphere brain activity. The other three had more activity on the left.

Right-brain advocates could argue that the results support their assertion that people with different brain styles attack the same problem with different hemispheres. Mazziotta sees it otherwise. "Even on the most trivial tasks," he says, "our studies showed that everything in the brain was in flux-both sides, the front and back, the top and bottom. It was tremendously complicated. To think that you could reduce this to a simple left-right dichotomy would be misleading and oversimplified."

The quarrel with the right-brain movement, Mazziotta and others say, isn't with the results its practitioners obtain. The actual business advice of companies like Inferential Focus and Herrmann's Whole Brain Corporation may be quite sound, and in any case the left-right distinction is an intriguing way of classifying thought processes. The problem arises when the right-brain movement implies that its conclusions are based on hard fact, rather than an essentially metaphorical interpretation of scientific discoveries. The differences between the hemispheres are still not well understood, and Gazzaniga, like Springer, says that the newest research tends to emphasize the way the two cooperate with one another during normal functioning, rather than how they differ.

Scientists are understandably annoved when they see careful but often inconclusive work popularized and exploited so glibly. As Deutsch puts it: "I get bothered by people saying 'This is all based on neurological theory, therefore it's true.' It's not legitimized by neurological theory. There is no evidence that people favor one portion of the brain or the other-that's pure speculation. And you can't justify the program in those terms." Let the rightbrain movement prove itself by showing that right-thinking managers make better decisions in the board room, these scientists say, rather than by appealing to what goes on in the lab. In the meantime, the prudent position may be the one that Gazzaniga only half-jokingly recommends: "The left hemisphere-don't leave home without it." 

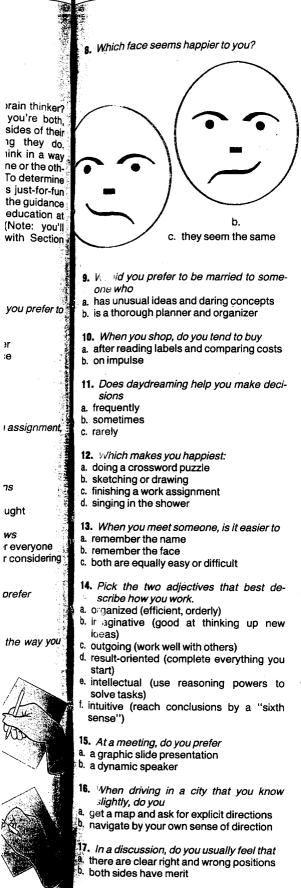

## WHICH SIDE **ARE YOU ON?**

Are you a left-brain or a right-brain thinker? Strictly speaking, of course, you're both, since normal people use both sides of their brains for virtually everything they do. Nevertheless, many people think in a way that scientists associate with one or the other of the brain's hemispheres. To determine your own thinking style, try this just-for-fun questionnaire, prepared under the guidance of Ivan Muse, a professor of education at Brigham Young University. (Note: you'll need a partner to help you with Section Three.)
